

SupportPilot AI — Product Requirements

AI-Assisted Customer Support & Ticket Management Platform

Product Overview

SupportPilot AI centralizes customer support tickets and assists agents with classification, routing, summaries, knowledge retrieval and suggested responses.

AI is positioned as an assistive layer. Customer-facing responses require human review in the initial release.

Core Requirements

Ticket creation, queue management, assignment, priority, SLA tracking, search, filters, audit history, customer profiles, conversation timelines, notifications, workflow automation, knowledge base, integrations, roles and reporting.

AI Requirements

The system can classify intent and priority, summarize conversations, retrieve approved knowledge and draft suggested responses. Low-confidence results should fall back to manual workflows.

AI interactions should be traceable by feature, version and review outcome, with controls for access boundaries and quality monitoring.

Operational Workflow

Customer request → ticket creation → classification → routing → agent review → knowledge-assisted response → status update → resolution → analytics and quality review.

Security & Governance

Role-based access, least privilege, audit logs, secure integrations, privacy controls, human-in-the-loop review, model evaluation and rollback mechanisms are core product requirements.

Prepared as a portfolio case-study artifact. Requirements and metrics are illustrative unless explicitly validated in a real implementation.
